Abstract

Hepatitis B infection is a worldwide healthcare problem, especially in developing areas. The current study was to evaluate the alterations in different biochemical parameters including paraoxonase (PON), 5’-Nucleotidase (5NT), total bilirubin, direct bilirubin, indirect bilirubin, Prothrombin time (PT), alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase (ALP), Total serum protein (TSP), albumin (Alb), Superoxide dismutase (SOD) and γ-glutamyl transpeptidase (GGT) in the serum samples of the viral hepatitis patients (n=100) compared with healthy controls(n=100). This study shown that there were significant increase (p<0.05) in the TSB, D. Bilirubin, In. Bilirubin, AST, ALT, PT, GGT, 5-NT, and ALP in viral hepatitis patients compared to their respective normal controls and there were significant decrease (p<0.05) in the serum (PON, SOD) activities, TSP and albumin concentration. It can be concluded that PON, 5-NT, SOD, ALT, AST, ALP and GGT may be specific method for making a diagnosis of viral hepatitis and also in distinguishing it with other kinds of hepatitis.

Keywords: Paraoxonase , 5’-Nucleotidase , viral hepatitis B.

1. Introduction

Hepatitis B is a potentially life-threatening infection that affects millions of individuals worldwide, it attacks the liver [1]. Both acute and chronic liver diseases can be caused by hepatitis B Virus (HBV)[2]. About 5–6% are persistent carriers of HBV and approximately 8% of the world's population has been infected with HBV [3]. Noncytocidal, chronic infection to hepatocytes are caused by HBV and this is one of the reasons for chronic HBV infections [4]. The viruses are continuously shed by hepatocytes into the bloodstream. Furthermore hepatocytes possess long-life, having 6 to 12 months or more. Hence, in the absence of a robust immune response, the combination of long-lived non-dividing host cell and a stable virus-host relationship virtually ensures the persistence of an infection [5]. Liver is one of the largest organs in the body. It has many important metabolic functions. Liver tissue has a relatively large amount of enzymes activity and alteration of various enzymes in hepatitis. Oxidative stress is a common pathogenic mechanism that participates to the development of hepatic damage in cases of hepatic inflammatory disorders, including acute and chronic hepatitis [6, 7]. Paraoxonase (PON) is known to be tightly bound with HDL in blood which belongs to a family of calcium-dependent antioxidant enzyme (lactonases/hydrolases) [8]. The aim of this study was to assess levels of PON, ALT, AST, ALP, and GGT in the patients with viral hepatitis patients compared with healthy controls.

2. Patients and Methods

This study includes 100 patients with Hepatitis B (58 men, 42 women), with a mean age of 40.34 ± 9.88 years and 100 healthy controls (57 men, 43 women, 46.12 ± 10.48), matched for sex and age were analyzed, admitted to Kirkuk Teaching Hospital (Kirkuk province), in a period from 12 September 2015 to 16 February 2016. Patients with neoplasia, diabetes, cardiovascular disease, and renal disease were excluded. Venous blood sample was acquired between 8 and 8:30 AM., Aspartate aminotransferase (AST) and alanine aminotransferase (ALT) were evaluated by Reitman and Frankel method [9]. The Estimation of GGT, and ALP were done by the methods as proposed by Szasz [10]., and King [11], respectively. Measurement of PON, 5’-nucleotidase, and PT were performed by according to the method described by Mackness et al, Campbell, and Quick [12-13, 14] respectively. The data was analyzed using SPSS-16 software package. Mean, and Standard deviation were applied.
3. Results

The Demographic Characteristics of serum samples of viral hepatitis patients and controls is summarized in Table 1.

4. Discussion

Study finding demonstrated a significantly high serum ALT, AST, GGT, ALP concentration but significantly low TSP, and PON in patients with viral hepatitis versus healthy controls. γ-glutamyltranspeptidase, a membrane enzyme found in the hepatobiliary system, that is essential for synthesis of glutathione, which is the main antioxidant molecule in cells, is controlled by GGT. In the presence of cholestasis in viral hepatitis, GGT increases more than 10 folds, whereas in absence of cholestasis, it increases up to 5 times [15]. ALT is the most reliable biochemical value to show the liver injury in patients with acute and chronic viral hepatitis, this is due to the distribution of cytoplasmic exclusively of ALT and longer half-life in the blood (about 50 hours) than for AST (about 16 hours) [16,17]. The possible mechanisms include Excretion of ALP is reduced in bile Will cause the in regurgitation of enzyme into circulation by the hepatic sinusoid [18, 19]. ALP increased in disease resembles the ALP which can be removed from liver. Production of ALP by the bile ductules cell is motivates via increased cholestasis that providing additional ALP which eventually enters the bloods, releasing of ALP from its membranes bound site and entry into
blood is facilitated due to amphillic nature of bile salts[20]. The Prothrombin time (PT) involves the time required for the platelet-poor plasma to clot after the addition of thromboplastin and calcium chloride. In our study, PT values in patients hepatitis B was significantly different with to those in healthy participants, in accordance with the result of [21,22] Which has sustained that prolong the clotting time is connected with the degree of inhibition of the integrity of both the entrinsic pathway of coagulation, consequently the grade of liver damage. A reduction in PON1 activity in patients with chronic hepatitis could be interpreted via the following mechanisms. Fist, serum PON1 activity (with normal hepatic PON1 concentration) would be lowered as a result of changes in synthesis or secretion of the HDL secondary. [23, 24]. Impaired synthesis and Changes in the structure of HDL connected to reduced serum PON1 levels in mice with impaired lecithin: cholesterol acyl transferase (LCAT) activity Because of LCAT gene-targeted disturbances [25]. Second, although the PON1 gene expression confined only to liver, as there is liver damage, it is clear that there is a defective gene expression, thereby causative to lower PON1 in these patients. It has been reported that there was significant decrease in PON1 activity in in rats with chronically administered CCl4 secondary to increased free radicles [26]. Superoxide dismutase plays a crucial role in the alleviation of H2O2 that was formed in RBC and because hemoglobin and SOD has been proven to be in closely linked in RBC. In the present results agree with other studies that have shown increased SOD level [27,28]. These findings indicate that the SOD may be cause free radical formation in hepatic diseases. 5’-Nucleotidaseis a glycoprotein as an ectoenzyme in mammalian cells. confined in cytoplasmic membrane [29,30], Significant increase in 5’Nucleotidase levels in chronic hepatitis B and suggest that the extent of damage to the liver. Subhani et al., [31] observed that higher level of 5’-NT in alcoholic consumers than in cirrhotic groups. Pratibha et al [32], found that increases serum level of acute infective hepatitis patients. Subhani TF [33], stated that 5’-NT were higher among chronic hepatitis C than Alcoholic patients.

5. Conclusions

Our results indicate a link between the damage of cells caused by decreased PON-1, and hepatitis B indicating a possible contributive role of these markers in the development of hepatitis B and as an indicator in the discrimination of hepatitis B from healthy controls. These findings need to be confirmed by further prospective longitudinal studies with adequate sample size. is capable of hydrolyzing oxidized lipids and thus protects against atherosclerosis.
